

DIANAX^{PRO}

DIANAX (Methandrostenolone)

Brand: ProLab

Pharmaceutical Form: Capsules

Presentation: Package with 100 capsules of 10 mg each

COMPOSITION:

Each Dianax tablet contains 10 mg of Methandrostenolone, an anabolic androgenic steroid derived from testosterone. This compound acts directly on the androgen receptors in muscle cells, stimulating increased protein synthesis and resulting in an accelerated increase in muscle mass. The Dianax formulation includes a series of excipients selected to optimize the stability of the product, its bioavailability and its pharmacokinetic profile. These excipients, which include bulking agents, binders and disintegrants, facilitate the rapid dissolution and absorption of the drug in the gastrointestinal tract. Dianax has been specifically designed for those seeking an effective combination of strength, muscle growth and superior physical performance.

THERAPEUTIC INDICATIONS:

Dianax is primarily indicated for the treatment of conditions where rapid lean muscle mass gain is required. It is commonly used by bodybuilders and high-performance athletes who wish to improve their levels of strength, endurance and physical capacity in a short period of time. This compound is also used in bulking phases, where workouts demand accelerated recovery and the body needs to increase its ability to repair damaged muscle tissue after intense sessions.

In addition, Dianax has been used in some clinical cases under medical prescription to treat conditions that lead to loss of muscle mass, such as severe catabolic diseases. This is due to its ability to stimulate nitrogen retention and improve positive nitrogen balance, crucial for muscle recovery.

RECOMMENDED DOSAGE:

The dosage of Dianax may vary depending on individual goals, previous experience with anabolic steroids, and personal tolerance. For beginner users, it is recommended to start with a dosage of 20 mg daily for the first week. This dosage allows the body to adjust to the compound and minimizes possible initial side effects. From the second week onwards, the dosage can be increased to 30 mg daily, spread over two or three doses throughout the day. This increase will help maximize anabolic effects without compromising safety.

For intermediate users who are already experienced with anabolic steroids, it is suggested to start directly with 30 mg daily for the first four weeks, divided into three doses. After this period, if no significant adverse effects occur, the dose can be increased to 40-50 mg daily. It is crucial to monitor the effects on the body, especially when increasing the dose.

Advanced users may opt for a dose of 50 mg daily, divided into three doses throughout the day. This dose represents the maximum recommended limit and should be administered with caution. It is advised that the cycle of use of Dianax lasts between six and eight weeks, avoiding prolonging the treatment beyond this time to minimize the risks associated with hepatotoxicity and other adverse effects. After completing a cycle, a rest period of 4 to 6 weeks should be observed to allow the body to recover and restore its natural hormonal balance. During this time, it is highly recommended to implement a Post-Cycle Therapy (PCT) Protocol to mitigate the suppressive effects on endogenous testosterone production.

ADMINISTRATION MODE:

Dianax should be administered orally, and it is important to ingest the tablets with a sufficient amount of liquid. To maximize the bioavailability of Methandrostenolone, it is recommended to take Dianax with food, preferably rich in healthy fats, as this can improve the absorption of the drug in the intestine. It is crucial that the doses are spread throughout the day to maintain a stable concentration in the blood plasma, avoiding sharp peaks that could lead to undesirable side effects.

CONTRAINDICATIONS:

The use of Dianax is contraindicated in patients with known hypersensitivity to Methandrostenolone or any of the excipients of the product. In addition, its use is not recommended in people who have active liver disease or a history of severe liver damage, such as hepatitis or cirrhosis. Those with severe renal impairment should also avoid this compound, as it may aggravate the renal condition and increase systemic toxicity.

Dianax is contraindicated in patients with uncontrolled hypertension, a history of myocardial infarction, or any other significant cardiovascular disease. It is also prohibited for use in pregnant or lactating women due to the risks of masculinization of the fetus and possible transmission of the compound through breast milk. It should also be avoided in people with pre-existing endocrine disorders, such as cancer.
